

# CSN-261:Data Structures Laboratory

## Assignment-2

Name-Rushiprasad Sanjiv Sagare

Class- B.Tech CSE

Sub Batch- O3

Enrollment No- 18114071

Email Id- [ssanjiv@cs.iitr.ac.in](mailto:ssanjiv@cs.iitr.ac.in)

## Problem1.

In this Problem, you have to implement a simple transposition cipher, where this cipher encrypts and decrypts a sequence of characters by dividing the sequence into blocks of size  $n$ , where  $n$  is specified by the encryption key. If the input text has a length that is not a multiple of  $n$ , the last block is padded with null characters ('\0'). In addition to  $n$ , the key also specifies two parameters  $a$  and  $b$ . For each block, the  $i$ -th output character, starting from 0 as usual, is set to the  $j$ -th input character, where  $j = (ai + b) \bmod n$ . For appropriate choices of  $a$  and  $b$ , this will reorder the characters in the block in a way that can be reversed by choosing a corresponding decryption key ( $n, a', b'$ ). For example, if  $n = 5$ ,  $a = 3$ , and  $b = 2$ , the string Hello, world! would be encrypted like this:

```
l: H e l l o ,   w o r l d ! \0 \0
i: 0 1 2 3 4 0 1 2 3 4 0 1 2 3 4
j: 2 0 3 1 4 2 0 3 1 4 2 0 3 1 4
out: l H l e o w , o r ! l \0 d \o
```

### Task to Perform:

Write a program `transpose.c` that takes  $n$ ,  $a$ ,  $b$ , `inputfile.txt` in `argv[1]`, `argv[2]`, `argv[3]`, and `argv[4]`, respectively, applies the above encryption; and writes the result to `outputfile.txt`. Further, write a program `inverseTranspose.c` that decrypt the `outputfile.txt` and result in a new file named `decryptedOutputfile.txt`. Finally, write a program `compareFiles.c` to find the equivalence between the `inputfile.txt` and `decryptedOutputfile.txt` files. You may assume that  $n$ ,  $a$ , and  $b$  are all small enough to fit into variables of type `int`. Your program should exit with a nonzero exit code if  $n$  is not at least 1 or if it is not given exactly four arguments, but you do not need to do anything to test for badly-formatted arguments. You should not make any other assumptions about the values of  $n$ ,  $a$ , or  $b$ ; for example, either of  $a$  or  $b$  could be zero or negative.

# Algorithms and Data Structures used in the implementation

## Data structure- 1D- Arrays

### Algorithm-

transpose.c :

=> Inputs for n,a,b,filename are taken as arguments.

=> File is read and the text is stored in a string.

=> This string is broken into  $\text{strlen}(\text{str})/n+1$  blocks if  $\text{strlen}\%n \neq 0$  else into  $\text{strlen}(\text{str})/n$  blocks.

=> Then by using transposition cipher , the text is encrypted.

inverseTranspose.c :

=>Inputs are given for n,a,b.

=>Using the values of n,a,b we can calculate values of a' and b' .

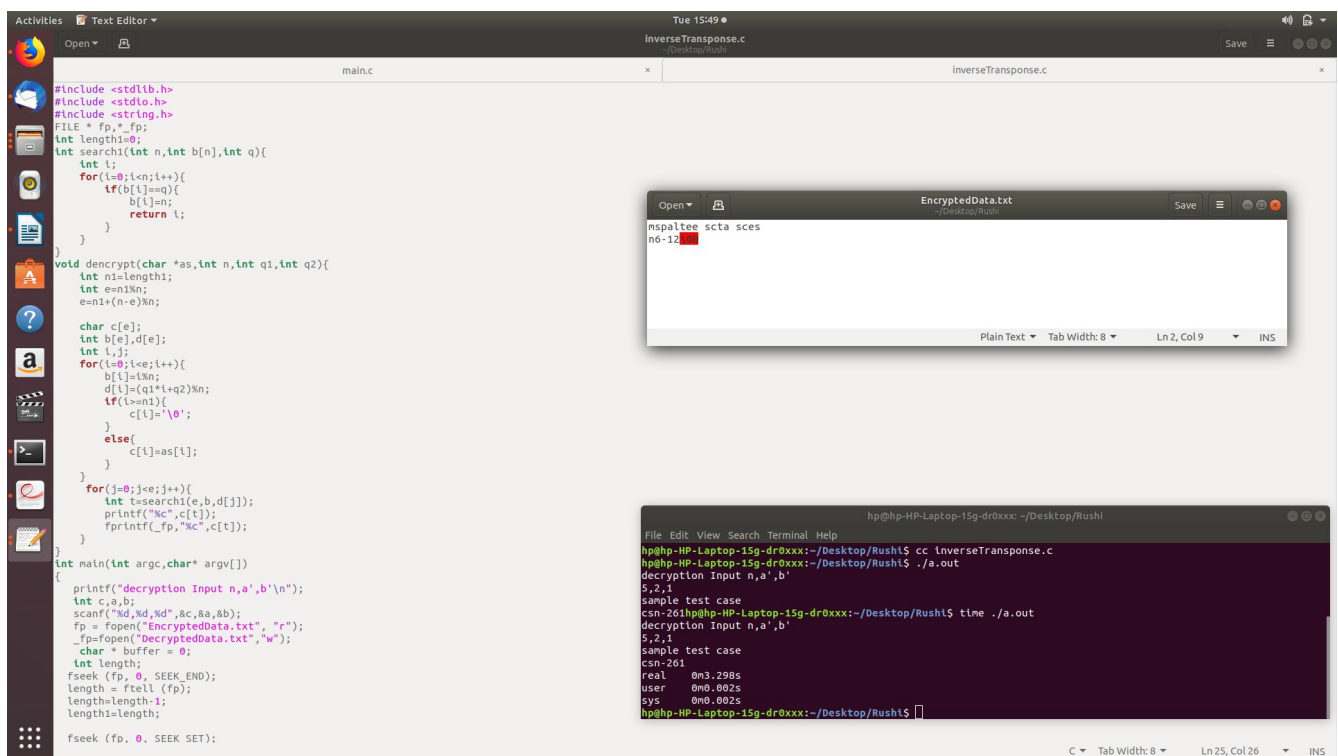

as  $i = a^{-1}(j-b) \bmod n$ .

therefore ,  $a' = a^{-1}$  ,  $b' = -(a^{-1}*b) \bmod n$

=> By using a' and b' we can decrypt the given encrypted text.

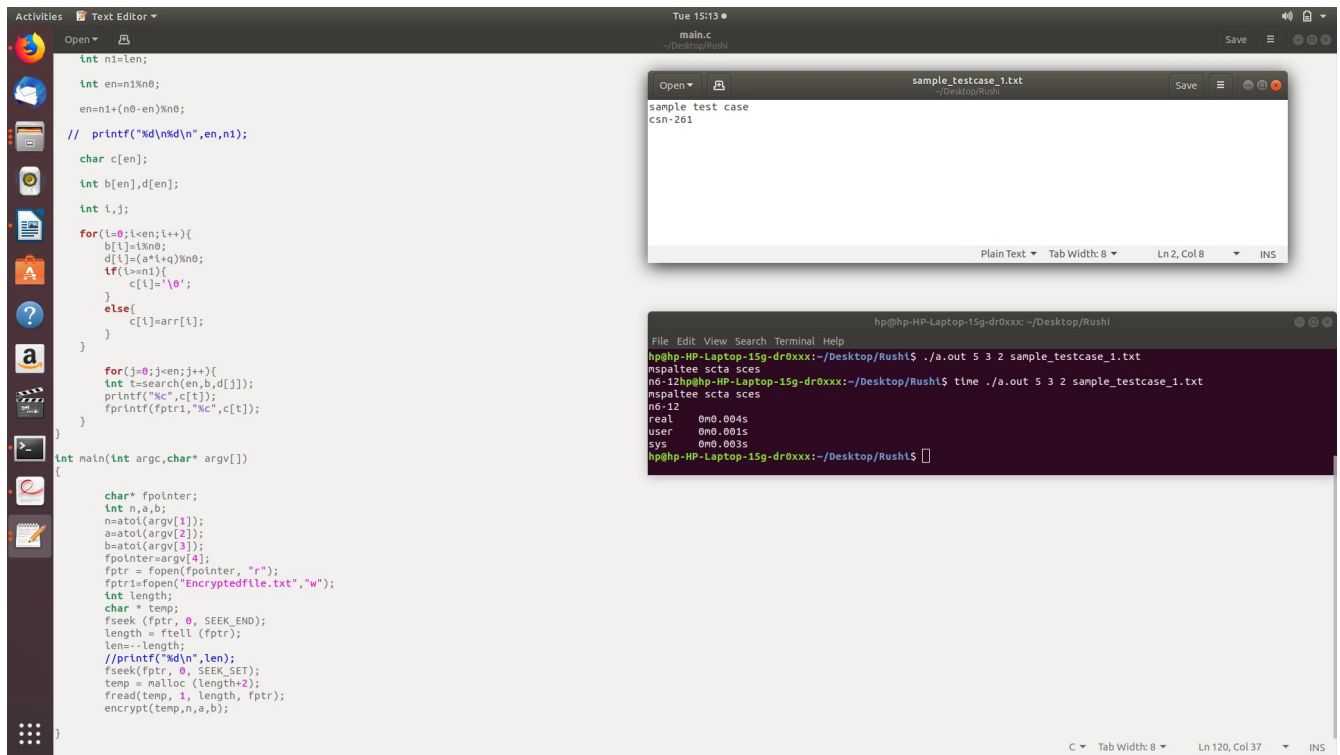

compare.c :

=> Here, inputfile.txt and decryptedOutputfile.txt are compared character to character.

The screenshot displays a Linux desktop environment with three windows open:

- main.c**: A C program for decrypting data using a transposition cipher. It includes headers for `stdlib.h`, `stdio.h`, and `string.h`. It defines a `search` function to find a character in a string and a `decrypt` function that uses a key 'a' and 'b' to reverse the encryption. The `main` function reads 'a' and 'b' from the user, opens 'EncryptedData.txt', and writes the decrypted output to 'decryptedOutputfile.txt'.
- EncryptedData.txt**: A text file containing the encrypted data: `m5paltee scta sces` and `n6-12`.
- Terminal**: A terminal window showing the execution of the program. It runs `cc inverseTranspose.c` to compile the program and `./a.out` to execute it. The output shows the program successfully decrypting the input 'm5paltee scta sces' and 'n6-12'.

## Problem2 : Medial axis transformation(MAT)

A region can be represented either by its interior or by its boundary. Here we represent the region by its interior using one of the most common methods called image array. In this case we have a collection of pixels. Since the number of elements in the array can be quite large, the main objective is to reduce its size by aggregating equal-valued pixels.

A general approach is to treat the region as a quadtree, where the region is represented as a union of maximal non-overlapping square blocks whose sides are in power of 2. The quadtree can be generated by successive subdivision of the image array into four equal sized quadrants. If the sub-array does not consist entirely of 1s or entirely of 0s, it is then further subdivided into quadrants and sub-quadrants, etc.

a region and its corresponding quadtree representation,

(a) Defined as the Sample region having all the bit value to 1.

(b) Defined as the binary array of size  $8*8$  which having bit value other than sample region within it is 0.

(c) Represent the conversion of binary array into the blocks where each block is formed as a union of

maximal square having the same bit value. This kind of array is called a maximal square array.

(d) Quadtree representation, where the root node corresponds to the entire array. Each son of a node represents a quadrant of the region represented by that node. The leaf nodes of the tree correspond to those blocks for which no further subdivision is necessary. A leaf node is said to be black or white, depending on whether its corresponding block is entirely inside or entirely outside of the represented region. All non-leaf nodes are said to be gray.

Task to perform: Write a C program, MAT.c to represent any region (in image array representation), into its quadtree form.

Input: Sample region is represented as  $n \times n$  array (as shown in Fig. 1 using  $6 \times 6$  matrix). The format of the input file should be as follows: the pixel values in the input file are separated by a single space and rows are separated by a newline character (refer to the sample L2\_P2\_inputsample.txt file shared in Piazza).

(Note: The  $6 \times 6$  region array should be mapped at the bottom-left corner of a  $8 \times 8$  binary array as shown in Fig. 2(b))

Output:

1. Print the Maximal square array where it should be filled in the following order: top-right, top-left, bottom-right and bottom-left quadrant, this should be done

recursively for all the sub-quadrants. All the cells within a maximal square block should be filled with its corresponding block number. For example, with respect to Fig. 2(c) maximal array should be represented as 2. Print the quadtree in the following manner, labels of leaf nodes, corresponding bit value and their level information (assuming the level of the root node to be 0), while traversing the quadtree in postorder. For example, in Fig. 2(d) the leaf node 3 having bit value 0 at level 2 and should be printed as (3,0,2).

Algorithm and Data Structures used:

Data structure : Quad Tree , 2-D array

Algorithm:

=> File is read and data is stored in 2-D array.

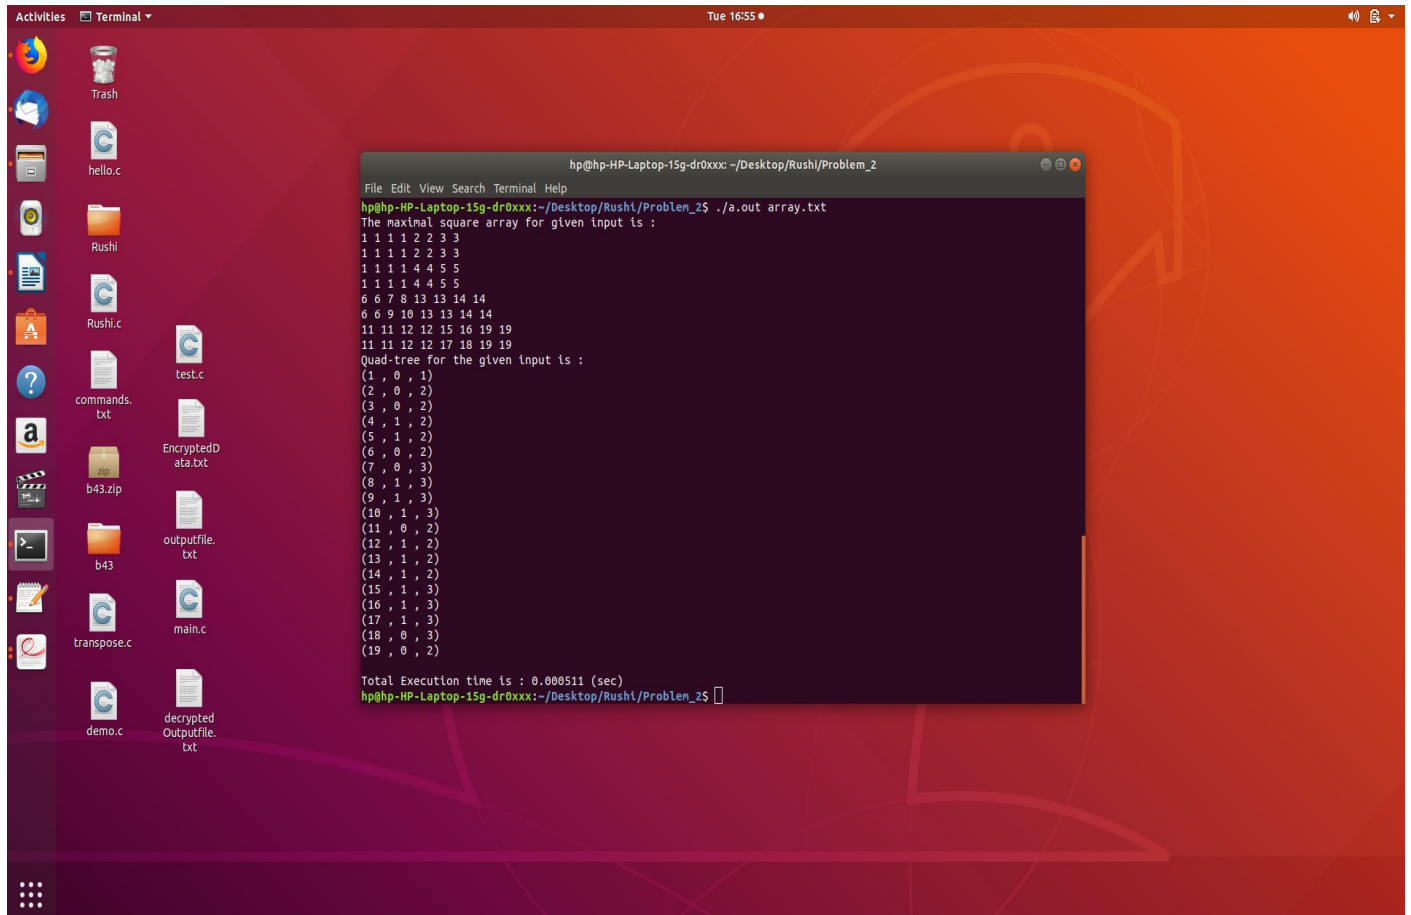

=> The  $n \times n$  array is converted into  $n' \times n'$  array where  $n'$  is the next power of 2.

=> The array is further divided into four equal sized quadrants.

=> Blocks where each value is same is represented by one value , else the block is further divided into 4 quadrants.

For example the leaf node 3 having bit value 0 at level 2 is printed as (3,0,2).
